

Thermodynamics Notes

2 – Thermal Energy, Temperature and Heat OH MY!

In the space below, create a **Venn Diagram** for the terms Thermal Energy, Temperature and Heat.

Include all the ways the terms are similar and different. *Start in pencil!*

intensive property

depends on the amount of matter

Thermal Energy (E_H): the sum total kinetic energy of all the moving atoms in a gas

Temperature (T): the average kinetic energy of the atoms in a gas.

$^{\circ}\text{C}$ vs. K	
<ul style="list-style-type: none"> Spacing between divisions is <u>the same</u>. Abs Zero (-273.15°C and 0 K) is the temp at which all particles <u>stop moving</u>. In labs, particles have been slowed to speeds corresponding to <u>$5 \times 10^{-10}\text{ K}$</u>. <p style="text-align: center; margin-top: 10px;">$^{\circ}\text{C} = \text{K} - 273.15$ OR $\text{K} = ^{\circ}\text{C} + 273.15$</p>	

Heat (Q): the transfers of thermal energy (caused by a difference in temp)

Thermal E is transferred from the faster moving atoms to the slower moving atoms.

The process is known as Heat.

Due to the Law of Conservation of Energy, Heat lost by one object must equal Heat gained by the second object.

Example:

Three samples of gases made of the same element, sample 1, sample 2 and sample 3, have the same thermal energy. Sample 1 has twice as many atoms as sample 2. Sample 3 has twice as many atoms as sample 1. What can you say about the temperatures of the three samples?

- a. $T_1 > T_2 > T_3$
- b. $T_3 > T_2 > T_1$
- c. $T_3 > T_1 > T_2$
- d. $T_2 > T_1 > T_3$
- e. $T_1 = T_2 = T_3$

Thermal E is the sum total!

Example:

The temperature of the gas (air) inside a basketball is increased when pumped up. This means that...

- a. Total E_K of the gas decreases and Avg. E_K of the molecules decreases
- b. Total E_K of the gas decreases and Avg. E_K of the molecules decreases
- c. Total E_K of the gas increases and Avg. E_K of the molecules increases
- d. Total E_K of the gas increases and Avg. E_K of the molecules decreases

Example:

Hydrogen has a boiling point of 20.28 K. Find its temperature in Celsius.

$$\begin{aligned} ^\circ\text{C} &= \text{K} - 273.15 \\ ^\circ\text{C} &= 20.28\text{K} - 273.15\text{K} \\ \boxed{^\circ\text{C} &= -252.87^\circ\text{C}} \end{aligned}$$

Example:

A piece of metal at exactly 80°C has its Celsius temperature tripled. By what does its Kelvin temperature increase?

$$\begin{aligned} \text{K} &= ^\circ\text{C} + 273.15 \\ \text{K} &= 240^\circ\text{C} + 273.15 \\ \boxed{\text{K} &= 513.15^\circ\text{C}} \\ \therefore \text{increase by } & 513.15^\circ\text{C} - 80^\circ \\ &= \boxed{433.15^\circ\text{C}} \end{aligned}$$

Before we go any further we must ask ourselves... what the heck is Thermodynamics?
